Approximation-generalization tradeoff

Small E_{out} : good approximation of f out of sample.

More complex $\mathcal{H} \Longrightarrow$ better chance of approximating f

Less complex $\mathcal{H}\Longrightarrow$ better chance of **generalizing** out of sample

Quantifying the tradeoff

VC analysis was one approach: $E_{
m out} \leq E_{
m in} + \Omega$

Bias-variance analysis is another: decomposing $E_{
m out}$ into

- 1. How well \mathcal{H} can approximate f
- 2. How well we can zoom in on a good $h \in \mathcal{H}$

Applies to real-valued targets and uses squared error

Start with $E_{\rm out}$

$$E_{\text{out}}(g^{(\mathcal{D})}) = \mathbb{E}_{\mathbf{x}} \Big[(g^{(\mathcal{D})}(\mathbf{x}) - f(\mathbf{x}))^2 \Big]$$

$$\mathbb{E}_{\mathcal{D}}\left[E_{\text{out}}(g^{(\mathcal{D})})\right] = \mathbb{E}_{\mathcal{D}}\left[\mathbb{E}_{\mathbf{x}}\left[\left(g^{(\mathcal{D})}(\mathbf{x}) - f(\mathbf{x})\right)^{2}\right]\right]$$
$$= \mathbb{E}_{\mathbf{x}}\left[\mathbb{E}_{\mathcal{D}}\left[\left(g^{(\mathcal{D})}(\mathbf{x}) - f(\mathbf{x})\right)^{2}\right]\right]$$

Now, let us focus on:

$$\mathbb{E}_{\mathcal{D}}\left[\left(g^{(\mathcal{D})}(\mathbf{x}) - f(\mathbf{x})
ight)^2
ight]$$

The average hypothesis

To evaluate
$$\mathbb{E}_{\mathcal{D}}\left[\left(g^{(\mathcal{D})}(\mathbf{x}) - f(\mathbf{x})\right)^2\right]$$

we define the 'average' hypothesis $\bar{g}(\mathbf{x})$:

$$ar{g}(\mathbf{x}) = \mathbb{E}_{\mathcal{D}}\left[g^{(\mathcal{D})}(\mathbf{x})
ight]$$

Imagine **many** data sets $\mathcal{D}_1, \mathcal{D}_2, \cdots, \mathcal{D}_K$

$$\bar{g}(\mathbf{x}) \approx \frac{1}{K} \sum_{k=1}^{K} g^{(\mathcal{D}_k)}(\mathbf{x})$$

Using $\bar{g}(\mathbf{x})$

$$\mathbb{E}_{\mathcal{D}}\left[\left(g^{(\mathcal{D})}(\mathbf{x}) - f(\mathbf{x})\right)^{2}\right] = \mathbb{E}_{\mathcal{D}}\left[\left(g^{(\mathcal{D})}(\mathbf{x}) - \bar{g}(\mathbf{x}) + \bar{g}(\mathbf{x}) - f(\mathbf{x})\right)^{2}\right]$$

$$= \mathbb{E}_{\mathcal{D}} \left[\left(g^{(\mathcal{D})}(\mathbf{x}) - \bar{g}(\mathbf{x}) \right)^2 + \left(\bar{g}(\mathbf{x}) - f(\mathbf{x}) \right)^2 \right]$$

+ 2
$$\left(g^{(\mathcal{D})}(\mathbf{x}) - \bar{g}(\mathbf{x})\right) \left(\bar{g}(\mathbf{x}) - f(\mathbf{x})\right)$$

$$= \mathbb{E}_{\mathcal{D}} \left[\left(g^{(\mathcal{D})}(\mathbf{x}) - \bar{g}(\mathbf{x}) \right)^{2} \right] + \left(\bar{g}(\mathbf{x}) - f(\mathbf{x}) \right)^{2}$$

Bias and variance

$$\mathbb{E}_{\mathcal{D}}\left[\left(g^{(\mathcal{D})}(\mathbf{x}) - f(\mathbf{x})\right)^{2}\right] = \underbrace{\mathbb{E}_{\mathcal{D}}\left[\left(g^{(\mathcal{D})}(\mathbf{x}) - \bar{g}(\mathbf{x})\right)^{2}\right]}_{\text{var}(\mathbf{x})} + \underbrace{\left(\bar{g}(\mathbf{x}) - f(\mathbf{x})\right)^{2}}_{\text{bias}(\mathbf{x})}$$

Therefore,
$$\mathbb{E}_{\mathcal{D}}\left[E_{\mathrm{out}}(g^{(\mathcal{D})})\right] = \mathbb{E}_{\mathbf{x}}\left[\mathbb{E}_{\mathcal{D}}\left[\left(g^{(\mathcal{D})}(\mathbf{x}) - f(\mathbf{x})\right)^2\right]\right]$$

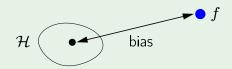

$$= \mathbb{E}_{\mathbf{x}}[\mathsf{bias}(\mathbf{x}) + \mathsf{var}(\mathbf{x})]$$

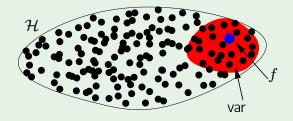

$$=$$
 bias $+$ var

The tradeoff

$$\mathsf{bias} = \mathbb{E}_{\mathbf{x}} \left[\left(ar{g}(\mathbf{x}) - f(\mathbf{x})
ight)^2
ight]$$

$$\mathsf{bias} = \mathbb{E}_{\mathbf{x}} \left[\left(\bar{g}(\mathbf{x}) - f(\mathbf{x}) \right)^2 \right] \qquad \mathsf{var} = \mathbb{E}_{\mathbf{x}} \left[\left. \mathbb{E}_{\mathcal{D}} \left[\left(g^{(\mathcal{D})}(\mathbf{x}) - \bar{g}(\mathbf{x}) \right)^2 \right] \right] \right]$$

$$\mathcal{H} \uparrow$$

Example: sine target

$$f:[-1,1] \to \mathbb{R}$$
 $f(x) = \sin(\pi x)$

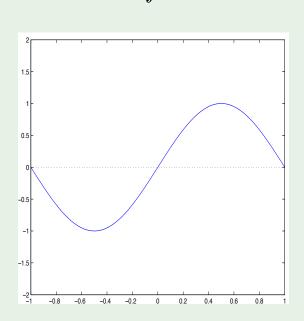

Only two training examples! N=2

Two models used for learning:

$$\mathcal{H}_0$$
: $h(x) = b$

$$\mathcal{H}_1$$
: $h(x) = ax + b$

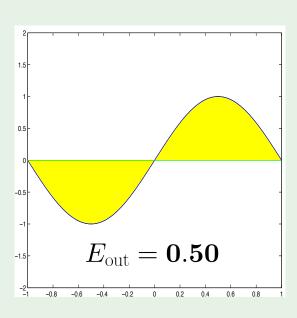

Which is better, \mathcal{H}_0 or \mathcal{H}_1 ?

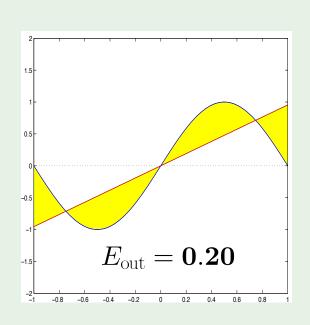

Approximation - \mathcal{H}_0 versus \mathcal{H}_1

 \mathcal{H}_0

 \mathcal{H}_1

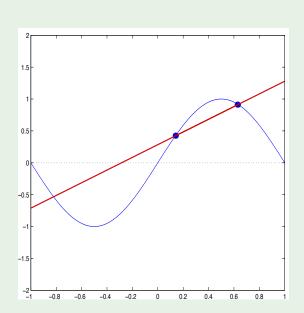

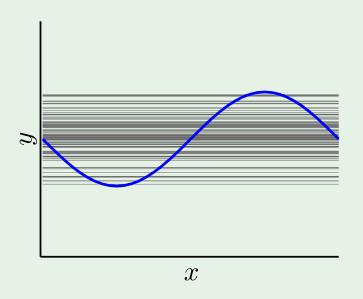

Learning - \mathcal{H}_0 versus \mathcal{H}_1

 \mathcal{H}_0 \mathcal{H}_1

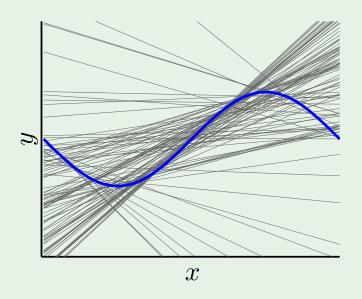

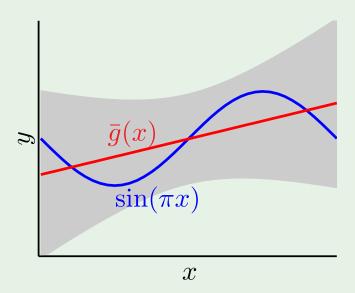

Bias and variance - \mathcal{H}_0

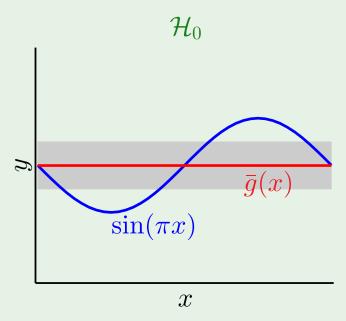

Bias and variance - \mathcal{H}_1

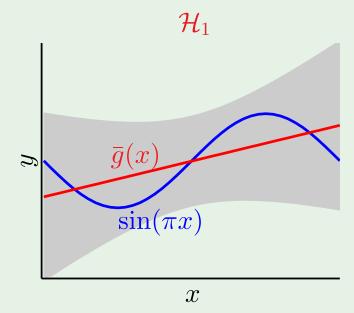

and the winner is ...

 $\mathsf{bias} = \mathbf{0.50}$

 $\mathsf{var} = \mathbf{0.25}$

 $\mathsf{bias} = \mathbf{0.21}$

 $\mathsf{var} = \mathbf{1.69}$

Lesson learned

Match the 'model complexity'

to the data resources, not to the target complexity

Outline

• Bias and Variance

• Learning Curves

Expected E_{out} and E_{in}

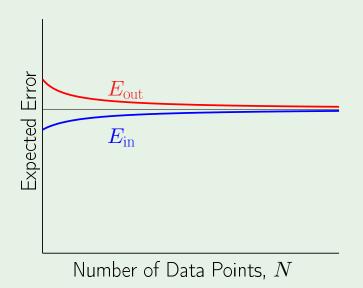

Data set \mathcal{D} of size N

Expected out-of-sample error $\mathbb{E}_{\mathcal{D}}[E_{\mathrm{out}}(g^{(\mathcal{D})})]$

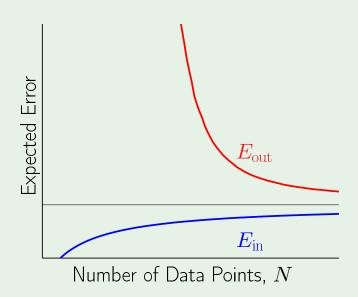

Expected in-sample error $\mathbb{E}_{\mathcal{D}}[E_{\mathrm{in}}(g^{(\mathcal{D})})]$

How do they vary with N?

20/22

Linear regression case

Noisy target $y = \mathbf{w}^{*\mathsf{T}}\mathbf{x} + \mathsf{noise}$

Data set
$$\mathcal{D} = \{(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_N, y_N)\}$$

Linear regression solution: $\mathbf{w} = (X^T X)^{-1} X^T \mathbf{y}$

In-sample error vector = $X\mathbf{w} - \mathbf{y}$

'Out-of-sample' error vector $= X\mathbf{w} - \mathbf{y}'$

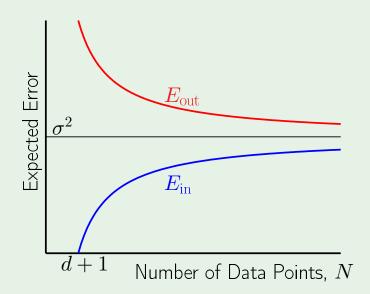

Learning curves for linear regression

Best approximation error $=\sigma^2$

Expected in-sample error $=\sigma^2\left(1-\frac{d+1}{N}\right)$

Expected out-of-sample error $=\sigma^2\left(1+\frac{d+1}{N}\right)$

Expected generalization error = $2\sigma^2 \left(\frac{d+1}{N}\right)$

Thank You!
